PROTEIN NETWORK COMPARATIVE GENOMICS

Trey Ideker
University of California San Diego

With the appearance of large networks of protein-protein and protein-DNA interactions as a new type of biological measurement, methods are needed for constructing cellular pathway models using interaction data as the central framework. The key idea is that, by comparing the molecular interaction network with other biological data sets, it will be possible to organize the network into modules representing the repertoire of distinct functional processes in the cell. Three distinct types of network comparisons will be discussed, including those to identify:

1. Protein interaction networks that are conserved across species
2. Networks in control of gene expression changes
3. Networks correlating with systematic phenotypes and synthetic lethals

Using these computational modeling and query tools, we are constructing network models to explain the physiological response of yeast to DNA damaging agents.
